### Decompositions

- Reduces redundancies and anomalies, but could have the following potential problems:
  - 1. Some queries become more expensive.
  - 2. Given instances of the decomposed relations, we may not be able to reconstruct the corresponding instance of the original relation!
  - 3. Checking some dependencies may require joining the instances of the decomposed relations.
- Two desirable properties:
  - Lossless-join decomposition
  - Dependency-preserving decomposition

## Lossless-join Decomposition

 Decomposition of R into X and Y is <u>lossless-join</u> w.r.t. a set of FDs F if, for every instance r that satisfies F:

 $\pi_{X}(r) \text{ join } \pi_{Y}(r) = r$ 

- In general one direction  $\pi_{\chi}(r)$  join  $\pi_{\gamma}(r) \supseteq r$  is always true, but the other may not hold.
- Definition extended to decomposition into 3 or more relations in a straightforward way.
- It is essential that all decompositions used to deal with redundancy be lossless! <u>(Avoids Problem</u> (2).)

### **Conditions for Lossless Join**

- The decomposition of R into X and Y is losslessjoin wrt F if and only if the closure of F contains:
  - $X \cap Y \rightarrow X$ , or
  - $X \cap Y \to Y$
- In particular, the decomposition of R into UV and R - V is losslessjoin if U → V holds over R.

## **Chase Test for Lossless Join**

- R(A,B,C,D) is decomposed into S1={A,D}, S2={A,C}, S3={B,C,D}
- Construct a Tableau
  - One row for each decomposed relation
  - For each row i, subcript an attribute with i if it does not occur in Si.
- FDs:  $A \rightarrow B$ ,  $B \rightarrow C$ ,  $CD \rightarrow A$
- Rules for "equating two rows" using FDs:
  - If one is unsubscripted, make the other the same
  - If both are subscripted, make the subscripts the same
- Goal: one unsubscripted row

Α	В	С	D	
а	b <sub>1</sub>	C <sub>1</sub>	d	S1
а	b <sub>2</sub>	С	$d_2$	S2
a <sub>3</sub>	b	С	d	S3

Α	В	С	D
а	b <sub>1</sub>	Ķ C	d
а	<b>X</b> ₂b₁	С	d <sub>2</sub>
<b>Ӽ</b> а	b	С	d

one unsubscripted row

imply lossless join

### **Dependency-preserving Decomposition**

<u>Student</u>	<u>Course</u>	Instructor		<u>Student</u>	<u>Instructor</u>		Course	<u>Instructor</u>
Smith	OS	Mark	$\rightarrow$	Smith	Mark		OS	Mark
$F=\{SC\toI,I\toC\}$				Checking	$\rm SC \rightarrow I re$	ן dr	uires a jo	oin!

- Dependency preserving decomposition (Intuitive):
  - If R is decomposed into X, Y and Z, and we enforce the FDs that hold on X, on Y and on Z, then all FDs that were given to hold on R must also hold. <u>(Avoids</u> <u>Problem (3).)</u>
- <u>Projection of set of FDs F</u>: If R is decomposed into X, ... projection of F onto X (denoted  $F_X$ ) is the set of FDs U  $\rightarrow$  V in F<sup>+</sup> (*closure of F*) such that U, V are in X.

### Dependency-preserving Decomp. (Cont)

- Decomposition of R into X and Y is <u>dependency</u> <u>preserving</u> if (F<sub>X</sub> union F<sub>Y</sub>) + = F +
  - i.e., if we consider only dependencies in the closure F<sup>+</sup> that can be checked in X without considering Y, and in Y without considering X, these imply all dependencies in F<sup>+</sup>.
- Important to consider F<sup>+</sup>, not F, in this definition:
  - ABC,  $A \rightarrow B$ ,  $B \rightarrow C$ ,  $C \rightarrow A$ , decomposed into AB and BC.
  - Is this dependency preserving? Is  $C \rightarrow A$  preserved?????
- Dependency preserving does not imply lossless join:
  - ABC,  $A \rightarrow B$ , decomposed into AB and BC.
- And vice-versa! (Example?)

### **Decomposition into BCNF**

- Consider relation R with FDs F. How do we decompose R into a set of small relations that are in BCNF ?
- Algorithm:
  - If X  $\rightarrow$  Y violates BCNF, decompose R into R-Y and XY
  - Repeat until all relations are in BCNF.
- Example: CSJDPQV, key C, JP $\rightarrow$ C, SD $\rightarrow$ P, J $\rightarrow$ S
  - To deal with J→S, decompose CSJDPQV into JS and CJDPQV
  - To deal with SD $\rightarrow$ P, decompose into SDP, CSJDQV
- Order in which we deal with the violating FD can lead to different relations!

### BCNF Decomposition Algorithm (3.20)

- Input: R<sub>0</sub>, set of FDs S<sub>0</sub>
- Output: A decomposition of R<sub>0</sub> into a collection of relations, all of which are in BCNF
- Initially  $R = R_0$ ,  $S = S_0$
- 1. If R is in BCNF, return {R}
- 2. Let  $X \rightarrow Y$  be a violation.
  - a. Compute X+.
  - b. Choose R<sub>1</sub>=X+
  - c. Let  $R_2 = X$  union (R-X+)
- 3. Compute FD projections  $S_1$  and  $S_2$  for  $R_1$  and  $R_2$
- 4. Recursively decompose  $R_1$  and  $R_2$  and return the union of the results

### **BCNF & Dependency Preservation**

• BCNF decomposition is lossless join, but there may not be a dependency preserving decomposition into BCNF

– e.g., CSZ, CS $\rightarrow$ Z, Z $\rightarrow$ C

- Can't decompose while preserving 1st FD; not in BCNF.
- Similarly, decomposition of CSJDQV into SDP, JS and CJDQV is not dependency preserving (w.r.t. the FDs JP C, SD→P and J→S).
  - However, it is a lossless join decomposition.
  - In this case, adding JPC to the collection of relations gives us a dependency preserving decomposition.
    - JPC tuples stored only for checking FD! (*Redundancy!*)

### Decomposition into 3NF

- Obviously, the algorithm for lossless join decomp into BCNF can be used to obtain a lossless join decomp into 3NF (typically, can stop earlier).
- How can we ensure dependency preservation ?
  - If  $X \rightarrow Y$  is not preserved, add relation XY.
  - Problem is that XY may violate 3NF! e.g., consider the addition of CJP to `preserve' JP $\rightarrow$ C. What if we also have J $\rightarrow$ C?
- Refinement: Instead of the given set of FDs F, use a *minimal cover for F*.

# Minimum Cover for a Set of FDs

- *Minimal cover or basis* G for a set of FDs F:
  - Closure of F = closure of G.
  - Right hand side of each FD in G is a single attribute.
  - If we modify G by deleting an FD or by deleting attributes from an FD in G, the closure changes.
- Intuitively, every FD in G is needed, and ``as small as possible'' in order to get the same closure as F.
- e.g., A → B, ABCD → E, EF→GH, ACDF → EG has the following minimal cover:
  - A $\rightarrow$ B, ACD $\rightarrow$ E, EF $\rightarrow$ G and EF $\rightarrow$ H

# **Computing the Minimal Cover**

- Algorithm
  - Put the FDs into standard form X → A. RHS is a single attribute.
  - Minimize the LHS of each FD. For each FD, check if we can delete an attribute from LHS while preserving F<sup>+</sup>.
  - 3. Delete redundant FDs.
- Minimal covers are not unique. Different order of computation can give different covers.
- e.g., A → B, ABCD → E, EF→GH, ACDF → EG has the following minimal cover:

– A $\rightarrow$ B, ACD $\rightarrow$ E, EF $\rightarrow$ G and EF $\rightarrow$ H

### 3NF Decomposition Algorithm (3.26)

- Input: R, set of FDs F
- **Output**: A decomposition of R into a collection of relations, all of which are in BCNF
- 1. Find a minimal basis/cover for F, say G
- 2. For each FD X  $\rightarrow$  A in G, use XA as one of the decomposed relations.
- 3. If none of the relations from Step 2 is a superkey for R, add another relation whose schema is a key for R.

# Summary of Schema Refinement

- If a relation is in BCNF, it is free of redundancies that can be detected using FDs. Thus, trying to ensure that all relations are in BCNF is a good heuristic
- If a relation is not in BCNF, we can try to decompose it into a collection of BCNF relations.
  - Must consider whether all FDs are preserved. If a lossless-join, dependency preserving decomposition into BCNF is not possible (or unsuitable, given typical queries), should consider decomposition into 3NF.
  - Decompositions should be carried out and/or reexamined while keeping *performance requirements* in mind.
