ICS 321 Spring 2011 SQL in a Server Environment

Asst. Prof. Lipyeow Lim Information & Computer Science Department University of Hawaii at Manoa

Three Tier Architecture

• Commonly used in large internet enterprises

SQL Environment

- Schemas : tables, views, assertions, triggers
 - CREATE SCHEMA <schema name>
 - Your login id is your default schema
 - SET SCHEMA <schema>
 - A fully qualified table name is <schema>.
- Catalogs : collection of schemas
 - Corresponds to "databases" in DB2
- Clusters : collection of catalogs
 - Corresponds to "database instance" in DB2

Client-Server Model

- CONNECT TO <server> AS <connection name> AUTHORIZATION
- DISCONNECT/CONNECT RESET/TERMINATE
- Session SQL operations performed while a connection is active

- Programming API
 - Generic SQL Interface
 - Embedded SQL in a host language
 - True Modules. Eg. Stored procedures.

SQL & Other Programming Languages

Two extremes of the integration spectrum:

- Highly integrated eg. Microsoft linq

 Compiler checking of database operations
- Loosely integrated eg. ODBC & JDBC
 - Provides a way to call SQL from host language
 - Host language compiler doesn't understand database operations.
- Requirements:
 - Perform DB operations from host language
 - DB operations need to access variables in host language

Networking Basics

Remote Client Access

- Applications run on a machine that is separate from the DB server
- DBMS "thin" client
 - Libraries to link your app to
 - App needs to know how to talk to DBMS server via network
- DBMS "full" client layer
 - Need to pre-configure the thick client layer to talk to DBMS server
 - Your app talks to a DBMS client layer as if it is talking to the server

What information is needed for 2 machines to talk over a network ?

Configuring DBMS Client Layer

- Tell the client where to find the server db2 CATALOG TCPIP NODE mydbsrv REMOTE 123.3.4.12 SERVER 50001
- Tell the client where to find the server

db2 CATALOG DATABASE bookdb AS mybookdb AT NODE mydbsrv Give a name for this node

Specify the IP address/hostnam e and the port number of the DB server machine

Specify the name of the database on the server

Give a local alias for the database Specify the name of the node that is associated with this database

Embedded SQL in C Programs

- DBMS-specific Preprocessor translates special macros to DBspecific function calls
- Pre-processor needs access to DBMS instance for validation.
- Executable needs to be bound to a specific database in a DBMS in order to execute

Connecting SQL & Host Language

- Need a way for host language to get data from SQL environment
- Need a way to pass values from host language to SQL environment
- Shared variables

 DECLARE SECTION
 In SQL, refer using
 :Salary, :EmployeeNo

EXEC SQL BEGIN DECLARE SECTION; char EmployeeNo[7]; char LastName[16]; double Salary; short SalaryNI; EXEC SQL END DECLARE SECTION;

An Example of Embedded SQL C Program

#include <stdio.h>
#include <string.h>
#include <sql.h>
int main()
{

// Include The SQLCA Data Structure Variable
EXEC SQL INCLUDE SQLCA;

// Define The SQL Host Variables Needed
EXEC SQL BEGIN DECLARE SECTION;

char EmployeeNo[7]; char LastName[16]; double Salary; short SalaryNI; EXEC SQL END DECLARE SECTION; // Connect To The Appropriate Database
EXEC SQL CONNECT TO SAMPLE USER
 db2admin USING ibmdb2;

// Declare A Static Cursor
EXEC SQL DECLARE C1 CURSOR FOR
SELECT EMPNO, LASTNAME, DOUBLE(SALARY)
FROM EMPLOYEE
WHERE JOB = 'DESIGNER';

// Open The Cursor
EXEC SQL OPEN C1;

An Example of Embedded SQL C Program

// If The Cursor Was Opened Successfully,
while (sqlca.sqlcode == SQL_RC_OK)

```
EXEC SQL FETCH C1 INTO :EmployeeNo,
:LastName, :Salary, :SalaryNI;
```

```
// Display The Record Retrieved
if (sqlca.sqlcode == SQL_RC_OK)
{
```

```
printf("%-8s %-16s ", EmployeeNo,
        LastName);
if (SalaryNI >= 0)
        printf("%lf\n", Salary);
else
        printf("Unknown\n");
```

// Close The Open Cursor EXEC SQL CLOSE C1; // Commit The Transaction EXEC SQL COMMIT; // Terminate The Database Connection EXEC SQL DISCONNECT CURRENT; // Return Control To The Operating System return(0);

```
}
```

- A cursor is an iterator for looping through a relation instance.
- Why is a cursor construct necessary ?

}

{

Updates

 SQL syntax except where clause require current of <cursor>

EXEC SQL BEGIN DECLARE SECTION; int certNo , worth ; char execName[31], execName[31], execAddr [256], SQLSTATE [6]; EXEC SQL END DECLARE SECTION; EXEC SQL DECLARE execCursor CURSOR FOR MovieExec; EXEC SQL OPEN execCursor while (1) { EXEC SQL FETCH FROM execCursor INTO :execName, :execAddr, :certNo, :worth; if (NO MORE TUPLES) break; if (worth < 1000) EXEC SQL DELETE FROM MovieExec WHERE CURRENT OF execCursor; else EXEC SQL **UPDATE** MovieExec **SET** netWorth=2*netWorth WHERE CURRENT OF execCursor;

EXEC SQL CLOSE execCursor

Static vs Dynamic SQL

 Static SQL refers to SQL queries that are completely specified at compile time. Eg.

// Declare A Static Cursor
EXEC SQL DECLARE C1 CURSOR FOR
SELECT EMPNO, LASTNAME,
DOUBLE(SALARY)
FROM EMPLOYEE
WHERE JOB = 'DESIGNER';

Dynamic SQL refers to SQL queries that are note completely specified at compile time. Eg. strcpy(SQLStmt, "SELECT * FROM EMPLOYEE WHERE JOB="); strcat(SQLStmt, argv[1]); **EXEC SQL** PREPARE SQL STMT FROM :SQLStmt; **EXEC SQL** EXECUTE SQL STMT;

Alternative to Embedded SQL

- What if we want to compile an application without the need for a DBMS-specific pre-compiler ?
- Use a library of database calls
 - Standardized (non-DBMS-specific) API
 - Pass SQL-strings from host language and presents result sets in a language friendly way
 - Eg. ODBC for C/C++ and JDBC for Java
 - DBMS-neutral
 - A driver traps the calls and translates them into DBMS-specific code

ODBC/JDBC Architecture

- Application
 - Initiates connections
 - Submits SQL statements
 - Terminates connections
- Driver Manager
 - Loads the right JDBC driver
- Driver
 - Connects to the data source,
 - Transmit requests,
 - Returns results and error codes
- Data Source
 - DBMS

4 Types of Drivers

- Type I: Bridge
 - Translate SQL commands to non-native API
 - eg. JDBC-ODBC bridge. JDBC is translated to ODBC to access an ODBC compliant data source.
- Type II: Direct Translation to native API via non-Java driver
 - Translates SQL to native API of data source.
 - Needs DBMS-specific library on each client.
- Type III: Network bridge
 - SQL stmts sent to a middleware server that talks to the data source. Hence small JDBC driver at each client
- Type IV: Direct Translation to native API via Java driver
 - Converts JDBC calls to network protocol used by DBMS.
 - Needs DBMS-specific Java driver at each client.

High Level Steps

- 1. Load the ODBC/JDBC driver
- 2. Connect to the data source
- 3. [optional] Prepare the SQL statements
- 4. Execute the SQL statements
- 5. Iterate over the resultset
- 6. Close the connection

Getting Data to/fro Host Language

- No declaration of shared variables
- Variables in host language is bound to columns of a SQL cursor
- ODBC
 - SQLBindCol gets data from SQL environment to host variables.
 - SQLBindParameter gets data from host variables to SQL environment
- JDBC
 - ResultSet class
 - PreparedStatement class

Prepare Statement or Not ?

String sql="SELECT * FROM books WHERE price < ?";
PreparedStatement pstmt = conn.prepareStatement(sql);
Pstmt.setFloat(1, usermaxprice);
Pstmt.executeUpdate();</pre>

- Executing without preparing statement
 - After DBMS receives SQL statement,
 - The SQL is compiled,
 - An execution plan is chosen by the optimizer,
 - The execution plan is evaluated by the DBMS engine
 - The results are returned
- conn.prepareStatement
 - Compiles and picks an execution plan
- pstmt.executeUpdate
 - Evaluates the execution plan with the parameters and gets the results

ResultSet

```
ResultSet rs = stmt.executeQuery(sqlstr);
while( rs.next() ){
        col1val = rs.getString(1); ...
```

- Iterate over the results of a SQL statement -- cf. cursor
- Note that types of column values do not need to be known at compile time

SQL Type	Java Class	accessor
BIT	Boolean	getBoolean
CHAR <i>,</i> VARCHAR	String	getString
DOUBLE, FLOAT	Double	getDouble
INTEGER	Integer	getInt
REAL	Double	getFloat
DATE	Java.sql.Date	getDate
TIME	Java.sql.Time	getTime
TIMESTAMP	Java.sql.TimeStamp	getTimestamp

RowSet

• When inserting lots of data, calling an execute statement for each row can be inefficient

A message is sent for each execute

- Many APIs provide a rowset implementation
 - A set of rows is maintained in-memory on the client
 - A single execute will then insert the set of rows in a single message
- Pros: high performance
- Cons: data can be lost if client crashes.
- Analogous rowset for reads (ie. ResultSet) also available

Stored Procedures

- What ?
 - A procedure that is called and executed via a single SQL statement
 - Executed in the same process space of the DBMS server
 - Can be programmed in SQL, C, java etc
 - The procedure is stored within the DBMS
- Advantages:
 - Encapsulate application logic while staying close to the data
 - Re-use of application logic by different users
 - Avoid tuple-at-a-time return of records through cursors

SQL Stored Procedures

CREATE PROCEDURE ShowNumReservations SELECT S.sid, S.sname, COUNT(*) FROM Sailors S, Reserves R WHERE S.sid = R.sid GROUP BY S.sid, S.sname

 Parameters modes: IN, OUT, INOUT
 CREATE PROCEDURE IncreaseRating (IN sailor_sid INTEGER, IN increase INTEGER)
 UPDATE Sailors
 SET rating = rating + increase
 WHERE sid = sailor_sid

Java Stored Procedures

CREATE PROCEDURE TopSailors (IN num INTEGER) LANGUAGE JAVA EXTERNAL NAME "file:///c:/storedProcs/rank.jar"

Calling Stored Procedures

- SQL: **CALL** IncreaseRating(101, 2);
- Embedded SQL in C: EXEC SQL BEGIN DECLARE SECTION int sid; int rating; EXEC SQL END DECLARE SECTION EXEC SQL CALL IncreaseRating(:sid, :rating);

• JDBC

CallableStatement cstmt = conn.prepareCall("{call Show Sailors}); ResultSet rs=cstmt.executeQuery();

• ODBC

SQLCHAR *stmt = (SQLCHAR *)"CALL ShowSailors"; cliRC = SQLPrepare(hstmt, stmt, SQL_NTS); cliRC = SQLExecute(hstmt);

User Defined Functions (UDFs)

- Extend and add to the support provided by SQL built-in functions
- Three types of UDFs
 - Scalar: returns a single-valued answer. Eg. Builting SUBSTR()
 - Column: returns a single-valued answer from a column of values. Eg. AVG()
 - Table: returns a table. Invoked in the FROM clause.
- Programable in SQL, C, JAVA.

Scalar UDFs

• Returns the tangent of a value

CREATE FUNCTION TAN (X DOUBLE) RETURNS DOUBLE LANGUAGE SQL CONTAINS SQL RETURN SIN(X)/COS(X)

• Reverses a string

CREATE FUNCTION REVERSE(INSTR VARCHAR(4000)) RETURNS VARCHAR(4000) CONTAINS SQL

```
BEGIN ATOMIC
   DECLARE REVSTR, RESTSTR
        VARCHAR(4000) DEFAULT ";
   DECLARE LEN INT;
   IF INSTR IS NULL THEN
        RETURN NULL;
   END IF;
   SET (RESTSTR, LEN) = (INSTR,
        LENGTH(INSTR));
   WHILE LEN > 0 DO
        SET (REVSTR, RESTSTR, LEN)
   = (SUBSTR(RESTSTR, 1, 1) CONCAT
   REVSTR, SUBSTR(RESTSTR, 2, LEN
  - 1), LEN - 1);
   END WHILE;
   RETURN REVSTR;
END
```

Table UDFs

 returns the employees in a specified department number. **CREATE FUNCTION** DEPTEMPLOYEES (DEPTNO CHAR(3)) **RETURNS TABLE** (EMPNO CHAR(6), LASTNAME VARCHAR(15), FIRSTNAME VARCHAR(12)) LANGUAGE SQL **READS SQL DATA** RETURN **SELECT** EMPNO, LASTNAME, FIRSTNME FROM EMPLOYEE WHERE EMPLOYEE.WORKDEPT = DEPTEMPLOYEES.DEPTNO

Java UDFs

CREATE FUNCTION tableUDF (DOUBLE) **RETURNS TABLE (** name VARCHAR(20), + job VARCHAR(20), 🕶 salary DOUBLE) **FXTFRNAL NAME** 'MYJAR1:UDFsrv!tableUDF' LANGUAGE JAVA PARAMETER STYLE DB2GENERAL NOT DETERMINISTIC FENCED NO SQL NO EXTERNAL ACTION **SCRATCHPAD 10** FINAL CALL DISALLOW PARALLEL **NO DBINFO@**

import COM.ibm.db2.app.UDF;

public void tableUDF(
double inSalaryFactor,
String outName,
String outJob,
double outNewSalary)

throws Exception

int intRow = 0;

...

}// tableUDF } // UDFsrv class
