# ICS 321 Spring 2011 <br> Overview of Storage \& Indexing (i) 

## Asst. Prof. Lipyeow Lim

Information \& Computer Science Department
University of Hawaii at Manoa

## Data Storage

- Main Memory
- Random access
- Volatile
- Flash Memory
- Random access
- Random writes are expensive
- Disk
- Random access
- Sequential access cheaper
- Tapes
- Only sequential access
- Archiving

## Cache

## Main Memory

Tertiary Storage

## Relational Tables on Disk

- Record -- a tuple or row of a relational table
- RIDs - record identifiers that uniquely identify a record across memory and disk
- Page - a collection of records that is the unit of transfer between memory and disk
- Bufferpool - a piece of memory used to cache data and index pages.
- Buffer Manager - a component of a DBMS that manages the pages in memory
- Disk Space Manager - a component of a DBMS that manages pages on disk

## Magnetic Disks

- A disk or platter contains multiple concentric rings called tracks.
- Tracks of a fixed diameter of a spindle of disks form a cylinder.
- Each track is divided into fixed sized sectors (ie. "arcs").
- Data stored in units of disk blocks (in multiples of sectors)
- An array of disk heads moves as a single unit.
- Seek time: time to move disk heads over the required track
- Rotational delay: time for desired sector to rotate under the disk head.
- Transfer time: time to actually read/write the data

## Accessing Data on Disk

- Seek time: time to move disk heads over the required track
- Rotational delay: time for

## Example: Barracuda 1TB HDD (ST31000528AS)

- What is the average time to read 2048 bytes of data?
= Seek time + rotational latency + transfer time
$=8.5 \mathrm{msec}+4.16 \mathrm{msec}+($ 2048 / 512 ) / 63 * ( 60 $000 \mathrm{msec} / 7200 \mathrm{rpm}$ )
$=8.5+4.16+0.265$

| cylinders | 121601 |
| :--- | :--- |
| Bytes/cylinder | $16065^{*} 512$ |
| Blocks/cylinder | 8029 |
| Sectors/track | 63 |
| Heads | 255 |
| Spindle Speed | 7200 rpm |
| Average <br> Latency | 4.16 msec |
| Random read <br> seek time | $<8.5 \mathrm{msec}$ |
| Random read <br> Write time | $<9.5 \mathrm{msec}$ |

## File Organizations

How do we organize records in a file ?

- Heap files: records not in any particular order
- Good for scans
- Sorted files: records sorted by particular fields
- scans in the sorted order or range scans in the sorted order
- Indexes: Data structures to organize records via trees or hashing.
- Like sorted files, they speed up searches for a subset of records, based on values in certain ("search key") fields
- Updates are much faster than in sorted files

## Comparing File Organizations

Consider an employee table with search key <age,sal>

- Scans : fetch all records in the file
- Point queries: find all employees who are 30 years old (let's assume there's only one such employee)
- Range queries: find all employees aged above 65.
- Insert a record.
- Delete a record given its RID.

## Analysis of Algorithms

- Computation model
- CPU comparison operation
- General: most expensive operation
- Worst-case
- How bad can it get ?
- Average-case
- Assumption about probabilities
- Analysis: count the number of some operation w.r.t. some input size
- Asymptotics: Big "O"
- Constants don't matter
$-500 n+10000=0(n)$

SELECT *
FROM Employees E
WHERE E.age=30

What is the worse case number of output tuples?

What is the worse case running time in the number of comparisons?

## Search Algorithms on Sorted Data

Shortcircuited Linear Search

Binary Search

```
(lo, hi) = (0,n-1)
mid = lo+(hi-lo)/2
While(hi>lo && E[mid].age!=30)
{
    if (E[mid].age < 30)
    {
        lo=mid
    }
    else
    {
        hi=mid
    }
    mid = lo+(hi-lo)/2
}
Output all satisfying tuples
around E[mid]
```

## Analysis of Binary Search

## What is the worse case?

$16,19,19,20,30,31,31,31,36$

$16,19,19,20,30,31,31,31,36$

```
(lo, hi) = (0,n-1)
mid = lo + (hi-lo)/2
While(hi>lo && E[mid].age!=30)
{
    if (E[mid].age < 30)
    lo=mid
    }
    else
        hi=mid
    }
    mid = lo + (hi-lo)/2
}
Output all satisfying tuples
around E[mid]
```

- Number tuples searched per iteration = n, n/2, n/4, ... 1
- Hence the number of iterations $=O(\log n)$
- Therefore number of comparisons $=\mathrm{O}(\log n)$

## Analysis of DBMS Algorithms

## Analysis Model

- B : number of data pages
- R : number of records per page
- D : average time to read/write a disk page
- From previous calculations, if a page is 2 K bytes, D is about 13 milliseconds
- C : average time to process a record
- For the 1 Ghz processors we have today, assuming it takes 100 cyles, C is about 100 nanoseconds

## Table Scans on Heap Files

```
for each page p of Employees table
{
    if (p not in bufferpool)
    {
    Fetch p from disk
    for each tuple t in page p
    {
        output t
        if (t.age==30)
        {
            output t
    }
    if (t.age>20 && t.age<30)
        {
            output t
    }
    }
}
```
